## (1) Hous

Rev B1, Page 1/15

## FEATURES

- 8-fold level shift up to 40 V output voltage
- Inputs compatible with TTL and CMOS levels, 40 V voltage proof
- Level shift configurable to $5 \mathrm{~V}, 10 \mathrm{~V}$ or supply voltage
- Short-circuit-proof push-pull current sources for driving FETs slowly
- Safe low output state with single errors
- Ground and supply voltage monitor
- Status output for error and system diagnostics
- Temperature range from -40 to $125^{\circ} \mathrm{C}$
- Protective ESD circuitry

## APPLICATIONS

- Operation of N-FETs from

$$
1.8 \mathrm{~V}, 2.5 \mathrm{~V}, 3.3 \mathrm{~V} \text { or } 5 \mathrm{~V} \text { systems }
$$

## PACKAGES

QFN24 $4 \mathrm{~mm} \times 4 \mathrm{~mm}$

## BLOCK DIAGRAM

## iC-MFN

## DESCRIPTION

iC-MFN is a monolithically integrated, 8-channel level adjustment device which drives N -channel FETs. The internal circuit blocks have been designed in such a way that with single errors, such as open pins (VB, VBR, GND, GNDR) or the short-circuiting of two outputs, iC-MFN's output stages switch to a predefined, safe low state. Externally connected N -channel FET are thus shut down safely in the event of a single error.

The inputs of the eight channels consist of a Schmitt trigger with a pull-down current source and are compatible with TTL and CMOS levels and are volt-age-proof up to 40 V . The eight channels have a cur-rent-limited push-pull output stage and a pull-down resistor at the output. The hi-level at one of the inputs EN5, EN10 or ENFS defines the output hi-level and enables the outputs. The output hi-level is disabled with the lo-level at all inputs EN5, EN10 and ENFS or with the hi-level at more than one input.
iC-MFN monitors the supply voltage at VB and VBR pin and the voltages at the two ground pins GND and GNDR. Both power supply pins VB and VBR and both pins GND and GNDR must be connected together externally in order to guarantee the safe low state of the output stages in the event of error.

Should the supply voltage at VB undershoot a predefined threshold, the voltage monitor causes the
outputs to be actively tied to GND via the low side transistors. If the ground potential ceases to be applied to GND, the outputs are tied to GNDR by pull-down resistors.

If the connection between the ground potential and the GND pin is disrupted, the high side and low side transistors of the output stages are shut down and the outputs tied to GNDR via the pull-down resistors. If on the other hand the connection between ground potential and the GNDR pin is disrupted, only the output stage high side transistors are shut down; the outputs are then actively tied to GND via the low side transistors.

Pull-down currents provide the safe lo-level at open inputs IN1...8, EN5, EN10 and ENFS. The pull-down currents have two stages in order to minimize power dissipation with enhanced noise immunity.

The status of the device is indicated with the Open-Drain pin NOK and can be used for system diagnostics.

Temperature monitoring protects the device from too high power dissipation.

The device is protected against destruction by ESD.

## PACKAGING INFORMATION

PIN CONFIGURATION QFN24-4x4 (topview)

PIN FUNCTIONS
No. Name Function
1 OUT1 Output channel 1
2 VB Supply Voltage
3 VBR Supply Voltage (R)
4 EN5 Enable input hi-level $=5 \mathrm{~V}$
5 EN10 Enable input hi-level $=10 \mathrm{~V}$
6 IN1 Input channel 1
7 IN2 Input channel 2
8 IN3 Input channel 3
9 IN4 Input channel 4
10 IN5 Input channel 5
11 IN6 Input channel 6
12 IN7 Input channel 7
13 IN8 Input channel 8
14 NOK Output inverted status
15 ENFS Enable input full scale hi-level = VB
16 GNDR Ground (R)
17 GND Ground
18 OUT8 Output channel 8
19 OUT7 Output channel 7
20 OUT6 Output channel 6
21 OUT5 Output channel 5
22 OUT4 Output channel 4
23 OUT3 Output channel 3
24 OUT2 Output channel 2
TP Backside Paddle

IC top marking: <P-CODE> = product code, <A-CODE> = assembly code (subject to changes), <D-CODE> = date code (subject to changes);

The Backside Paddle is to be connected to a ground plane on the PCB. Connections between GND, GNDR and the ground plane should be concidered with system FMEA aspects.

## ELECTRICAL CHARACTERISTICS: Diagrams

Figure 1: Propagation delays

## DESCRIPTION OF FUNCTIONS

## Hi-level output configuration

The device iC-MFN has three adjustable hi-levels for driving N -channel FETs. The configured hi-level is common to all outputs OUTx and the maximum level is the power supply VB potential. The hi-level configuration inputs are used simultaneous for enabling the hi-level at the outputs OUTx. The hi-level at exactly one input EN5, EN10 or ENFS configure the voltage of hi-level and enable the outputs. If more than one of these inputs have hi-level the outputs remains disabled. The hi-level 5 V (configured with EN5 $=\mathrm{hi}$ ) and 10 V (configured with EN10 $=\mathrm{hi}$ ) are internally generated by a voltage reference and regulated. The hi-level VB (configured with ENFS $=\mathrm{hi}$ ) is an unregulated connection to VB. In this case the voltage swing depends directly from the power supply VB.

## Output characteristics of the high side transistor

The high side output transistors at the eight channels demonstrate a resistive behavior with low voltage (VB $-\mathrm{V}(\mathrm{OUTx})$ ) and behave as a current source with finite output resistance with higher voltages.

Figure 2: Output characteristic of the high side transistor at OUTx

Figure 3: Output characteristic of the regulated push-pull-output at OUTx

## Output characteristic of the low side transistor

The low side output transistors at the eight channels demonstrate a resistive behavior with low voltage V (OUTx) and behave as a current sink with finite output resistance with higher voltages.

Figure 4: Output characteristic of the low side transistor at OUTx

## Status output NOK

The status output NOK is a current limited 40 V proof open-drain output. The output transistor is switched on if the hi-level of the outputs OUTx are enabled with exactly one pin ENx, the outputs have reached the voltage levels defined by the inputs INx , the power supply voltage is above the power-on threshold, the temperature is below the switch off temperature and all power supply pins are connected.

## Output characteristic of the regulated push-pul-l-output at OUTx

The hi-level 5 V and 10 V is generated with a regulated push-pull output and demonstrate a resistive behavior with low voltage changes and behave as a current source with finite output resistance with higher voltage changes.

Rev B1, Page 11/15

## Pull-down currents

In order to enhance noise immunity with limited power dissipation at inputs INx, EN5, EN10 and ENFS the pul-I-down currents at these pins have two stages. With a rise in voltage at input pins INx, EN5, EN10 and ENFS the pull-down current remains high until $\mathrm{Vt}($ ) hi (Electrical Characteristics No. 203); above this threshold the device switches to a lower pull-down current. If the voltage falls below $\mathrm{Vt}($ ()lo (Electrical Characteristics No. 204), the device switches back to a higher pull-down current.

Figure 5: Pull-down currents at INx, EN5, EN10 and ENFS

## DETECTING SINGLE ERRORS

If single errors are detected, safety-relevant applications require externally connected switching transistors to be specifically shut down. Single errors can occur when a pin is open (due to a disconnected bonding wire or a bad solder connection, for example) or when two pins are short-circuited.

When two output of different logic levels are short-circuited, the driving capability of the low side driver will predominate, keeping the connected N -channel FETs in a safe shutdown state.

With open pins VB, VBR, GND or GNDR iC-MFN switches the output stages to a safe, predefined low state via pull-down resistors and current sources at the outputs, subsequently shutting down any externally connected N -channel FETs.

## Loss of VB potential

If power supply potential is no longer applied to the VB-pin, the output stage high side drivers are shut down and the outputs actively tied to GND via the low side drivers.

## Loss of VBR potential

If power supply potential is no longer applied to the VBR-pin, the output stage high side drivers are shut down and the outputs actively tied to GND via the low side drivers.

## Loss of GNDR potential

If ground potential is no longer applied to the GNDR-pin, the output stage high side drivers are shut down and the outputs actively tied to GND via the low side drivers.

Figure 6: Output characteristics at OUTx with loss of VB, VBR or GNDR

## Loss of GND potential

If ground potential is not longer applied to GND, the output stages are shut down and the outputs tied to GNDR via current sources and internal pull-down resistors with a typical value of $200 \mathrm{k} \Omega$.

Figure 7: Output characteristics at OUTx with loss of GND

## APPLICATION NOTES

## Driving an N-channel MOSFET

One typical field of application for iC-MFN is in the operation of N -FETs with microprocessor output signals, as shown in Figure 8.

Figure 8: Driving an N-channel MOSFET

Slowly switching of a transistor is done with a current limited driver. Figure 9 shows the different phases of a turn on process with resistive load. In Section t0 to t 1 the gate of the transistors is loaded to the threshold voltage Vth(FET) and is a dead time. In section t1 to t2 the gate voltage keeps nearly constant (miller-plateau) during the drain voltage slope. The slew rate depends on the current of the driver and the gate-drain capacitor of the transistor. In section t2 to t3 the gate voltage reach the static value. The transistor thus goes low ohmic and minimizes the power dissipation. The equations 1 to 4 are simplified and give an estimation of the timing on the basis of data from the specifications of the device iC-MFN and the used transistor. The turn off looks similar to the turn on but with reverse run trough.

Figure 9: On switching of a transistor
$t_{o n}=$ overall turn on time [ $\mu \mathrm{s}$ ]
$V B=$ power supply $\mathrm{VB}[\mathrm{V}]$
$\operatorname{Vr}(O U T x)=$ configured static turn on voltage at OUTx [V]
$V_{t h}(F E T)=$ threshold of the transistor [V]

$$
\begin{equation*}
t_{t 0 . . t 1}[\mu s]=C_{\mathrm{iss}} @\left(V_{d s}=h i\right) \times \frac{V_{t h}(F E T)}{-\operatorname{Isc}(O U T \mathrm{x}) h i} \tag{1}
\end{equation*}
$$

$$
\begin{gather*}
t_{t 1 . . t 2}[\mu s]=C_{r s s} @\left(V_{d s}=h i\right) \times \frac{V B}{-\operatorname{Isc}(O U T x) h i}  \tag{2}\\
t_{t 2 . . t 3}[\mu s]=C_{\text {iss }} @\left(V_{d s}=l o\right) \times \frac{V r(O U T \mathrm{x})-V_{t h}(F E T)}{-\operatorname{Isc}(O U T x) h i} \tag{3}
\end{gather*}
$$

$$
\begin{equation*}
t_{o n}=t_{t 0 . . t 1}+t_{t 1 . . t 2}+t_{t 2 . . t 3} \tag{4}
\end{equation*}
$$

$C_{i s s}=C_{g s}+C_{g d}=$ voltage dependent gate-source and gate-drain capacitor [ nF ]
$C_{\text {rss }}=C_{g d}=$ voltage dependent gate-drain capacitor [nF]
$\operatorname{Isc}($ OUTx $) l o=$ short circuit current lo at OUTx [mA]
$t_{t 0 . . t 1}=$ dead time $[\mu \mathrm{s}]$
$t_{t 1 . . t 2}=$ slope time at drain (Miller-Plateau) [ $\mu \mathrm{s}$ ]
$t_{t 2 . . t 3}=$ time to reach static gate voltage [ $\mu \mathrm{s}$ ]

Rev B1, Page 13/15

## Example

Turn on calculation with following estimations:
$C_{\text {iss }} @\left(V_{d s}=24 \mathrm{~V}\right)=1.5 \mathrm{nF}$
$C_{\text {iss }} @\left(V_{d s}=1 \mathrm{~V}\right)=3 \mathrm{nF}$
$C_{r s s} @\left(V_{d s}=24 V\right)=0.3 \mathrm{nF}$
Isc(OUTx)hi $=-4 \mathrm{~mA}$
$V B=24 \mathrm{~V}$
$\operatorname{Vr}($ OUTx $)=10 \mathrm{~V}$
$V_{t h}(F E T)=3 \mathrm{~V}$

From this follows:
$t_{t 0 . . t 1}=1.13 \mu \mathrm{~s}$
$t_{t 1 . . t 2}=1.8 \mu \mathrm{~s}$
$t_{t 2 . . t 3}=5.25 \mu \mathrm{~s}$
$t_{o n}=8.18 \mu \mathrm{~s}$

The slew rate at the drain of transistor is: $13.3 \mathrm{~V} / \mu \mathrm{s}$
Figure 10 shows the turn on and off at one channel with pin INx. The pulse duration at pin NOK, especially at turn on, can be used for monitoring the connected transistor and the load.

Figure 10: Turn on and off one channel with INx
